

New methods for verb valence extraction from Polish texts

Łukasz Dębowski, Marcin Woliński
{ldebowsk,wolinski}@ipipan.waw.pl

Institute of Computer Science, Polish Academy of Sciences

1 Introduction

2 Our method

3 Evaluation

The problem

- Various resources are needed to parse a text in a natural language: grammars, dictionaries, etc.

Jasio **podziękował** Marysi za współpracę.

(Johnny thanked Mary for cooperation.)

Marysia **odpowiedziała** mu, że nie ma za co.

(Mary answered him: "Not at all".)

- The valence dictionary is one of them.

odpowiedzieć: np(nom), np(dat), ZE

podziękować: np(nom), np(dat), za+np(acc)

- Several valence dictionaries for Polish have been published.
- Is it possible to extract a better dictionary from a corpus?

Valence frames

*Johny was somewhat **surprised** by the answer...*

Odpowiedź **dziwiła** Jasia dwa tygodnie.

Jasia **dziwiło**, że Marysia tak odpowiedziała.

Jasio **dziwił** się i dziwił.

Jasio **dziwił** się i Marysi, i odpowiedzi.

Jasio **dziwił** się także, że się tak długo dziwi.

$$F(\text{dziwić}) = \left\{ \begin{array}{l} \{\text{np}(\text{nom}), \text{np}(\text{acc})\}, \\ \{\text{ZE}, \text{np}(\text{acc})\}, \\ \{\text{np}(\text{nom}), \text{sie}\}, \\ \{\text{np}(\text{nom}), \text{sie}, \text{np}(\text{dat})\}, \\ \{\text{np}(\text{nom}), \text{sie}, \text{ZE}\} \end{array} \right\}$$

Valence is hard to describe

- 1 Certain arguments must not co-occur.
- 2 It is difficult to enumerate all frames.
- 3 Some arguments can be dropped.
- 4 Some arguments are required.
- 5 The argument/adjunct distinction is vague:

Odpowiedź brzmiała dziwacznie.

- 6 Equivalence classes of arguments depend on the verb:

Jasio dziwił się { że Marysia tak odpowiedziała.
jej odpowiedzi.

Brent (1993)

Input: a corpus of raw texts,
a deterministic shallow parser.

$c(\mathbf{v}, \mathbf{f})$ — the count of parses that contain frame \mathbf{f} and verb \mathbf{v} ,
 $c(\mathbf{v}) = \sum_{\mathbf{f}} c(\mathbf{v}, \mathbf{f})$ — the count of parses that contain \mathbf{v} .

We will consider \mathbf{f} a frame for \mathbf{v} if and only if

$$\sum_{n=c(\mathbf{v},\mathbf{f})}^{c(\mathbf{v})} \binom{c(\mathbf{v})}{n} p_{\mathbf{f}}^n (1 - p_{\mathbf{f}})^{c(\mathbf{v})-n} \leq 0.05,$$

where $p_{\mathbf{f}}$ is selected in supervised or unsupervised learning:

- 1 to minimize the error rate on a training dictionary,
- 2 so that binomial distribution $\mathbf{B}(\cdot, p_{\mathbf{f}})$ fits into the first cluster in the histogram of verbs grouped by rate $c(\mathbf{v}, \mathbf{f})/c(\mathbf{v})$.

1 Introduction

2 Our method

3 Evaluation

The scheme of our approach

- 1 The Świgra parser is used to analyse raw text.
- 2 Parse forests are reduced to sets of valence frames.
- 3 The sets are disambiguated with a new EM selection algorithm.
- 4 The occurrences of frames and verbs are counted.
- 5 Supervised learning is used to find the sets of possible and required arguments.
- 6 The sets of valence frames are corrected in the next step.

Parsing

The sentences were selected from the IPI PAN Corpus of Polish.

We used a permissive version of the Świgra parser:

- ≤ 1 subject and any number of other arguments.

We selected sentences that

- contained ≤ 15 words,
- could be analysed in ≤ 1 minute,
- had ≤ 40 parses per elementary sentence.

Only ≤ 5000 sentences per verb were considered.

The reduction of parse trees to valence frames

We deleted parses that contained:

- *to, co, nic* (= *this, what, nothing*),
- highly improbable interpretations of ambiguous words.

The remaining parses were transformed:

- Phrases that are not children of the verb were deleted.
- The dropped personal subject was added.
- The genitive of negation was treated.
- Some NPs and PPs were marked as adjuncts.
- Lemmas of the phrase heads were removed.

The bank of reduced parse forests

- The bank consists of **510 743** elementary sentences.
- Świgrą has processed about **2.6** times more sentences.
- About **3.3** million running words.

'Kto zastąpi piekarza?' ('Who will replace the baker?')

zastąpić :np:acc: :np:nom:

zastąpić :np:gen: :np:nom:

'Nie płakał na podium.' ('He did not cry on the podium')

płakać :np:nom: :prepn:na:acc:

płakać :np:nom: :prepn:na:loc:

The EM selection

\mathbf{Y}_i — the set of parses for the i -th sentence, $i = 1, 2, \dots, M$.

$\mathbf{p}_j^{(n)}$ — the frequency of parse \mathbf{j} in the n -th iteration, $\mathbf{p}_j^{(1)} = 1$.

$$\mathbf{p}_{ji}^{(n)} = \begin{cases} \mathbf{p}_j^{(n)} / \sum_{j' \in \mathbf{Y}_i} \mathbf{p}_{j'}^{(n)}, & \mathbf{j} \in \mathbf{Y}_i, \\ \mathbf{0}, & \text{else,} \end{cases}$$

$$\mathbf{p}_j^{(n+1)} = \sum_{i=1}^M \mathbf{p}_{ji}^{(n)}.$$

sampling	accuracy
the shortest frame with maximal $\mathbf{p}_{ji}^{(n)}$	72.6%
the frame with maximal $\mathbf{p}_{ji}^{(n)}$	72.4%
the shortest frame	57.5%
blind	46.9%

Tested on 190 sentences, 500 Monte Carlo simulations, $\mathbf{n} = 10$.

Other applications of the EM selection

The EM selection may be used in many NLP applications.
E.g., for morphological disambiguation without a training set:

Y_i — possible interpretations for the i -th token, $i = 1, 2, \dots, M$.
 $p_j^{(n)}$ — the frequency of interpretation j in the n -th iteration.

$$p_{ji}^{(n)} = \begin{cases} p_j^{(n)} / \sum_{j' \in Y_i} p_{j'}^{(n)}, & j \in Y_i, \\ 0, & \text{else,} \end{cases}$$
$$p_j^{(n+1)} = \sum_{i=1}^M p_{ji}^{(n)}.$$

$$L^{(n+1)} \geq L^{(n)} \text{ for } L^{(n)} = \sum_{i=1}^M \log \left[\sum_{j \in Y_i} p_j^{(n)} \right].$$

The local maxima form a convex set so setting $p_j^{(1)}$ doesn't matter.

The proto-dictionary, the training data, and the test data

The proto-dictionary (counts of parses in the disambiguated bank):

```
'przyłapać' => { (= 'to catch smb red-handed')  
  'np(acc),np(gen),np(nom)' => 1,  
  'na+np(loc),np(nom),sie' => 1,  
  'na+np(loc),np(gen),np(nom)' => 1,  
  'np(acc),np(nom)' => 4,  
  'adv,np(nom)' => 1,  
  'na+np(loc),np(acc),np(nom)' => 3  
}
```

The training set:

- valence frames for **1166** verbs according to Świdziński (1994).

The test set:

- valence frames for **203** verbs according to the dictionaries by Polański (1980), Świdziński (1994), and Bańko (2000).

A new description of verb valence

$$F(\textit{przytapać}) = \left\{ \begin{array}{l} \{\textit{np(nom), np(acc)}\}, \\ \{\textit{np(nom), np(acc), na+np(loc)}\}, \\ \{\textit{np(nom), sie, na+np(loc)}\} \end{array} \right\}$$

We approximate $F(\mathbf{v})$ with three objects:

- 1 $L(\mathbf{v})$ — the set of possible arguments for \mathbf{v} ,
- 2 $E(\mathbf{v})$ — the set of required arguments for \mathbf{v} ,
- 3 $M(\mathbf{v}) : L(\mathbf{v}) \times L(\mathbf{v}) \rightarrow \{\leftarrow, \rightarrow, \leftrightarrow, \times, \perp\}$
— co-occurrence matrix for the arguments of \mathbf{v} .

The cells of the co-occurrence matrix depend weakly on the verb.

The sets of arguments

$$F(\textit{przytapać}) = \left\{ \begin{array}{l} \{\textit{np(nom), np(acc)}\}, \\ \{\textit{np(nom), np(acc), na+np(loc)}\}, \\ \{\textit{np(nom), sie, na+np(loc)}\} \end{array} \right\}$$

$$L(\mathbf{v}) := \bigcup_{f \in F(\mathbf{v})} f$$

$$E(\mathbf{v}) := \bigcap_{f \in F(\mathbf{v})} f$$

The co-occurrence matrix

$$F(\text{przytapać}) = \left\{ \begin{array}{l} \{\text{np(nom), np(acc)}\}, \\ \{\text{np(nom), np(acc), na+np(loc)}\}, \\ \{\text{np(nom), sie, na+np(loc)}\} \end{array} \right\}$$

Let $\langle \mathbf{a} \rangle := \{\mathbf{f} \in \mathbf{F}(\mathbf{v}) \mid \mathbf{a} \in \mathbf{f}\}$ and

$$\mathbf{a} \times \mathbf{b} \iff \langle \mathbf{a} \rangle \cap \langle \mathbf{b} \rangle = \emptyset, \quad (\mathbf{a} \text{ excludes } \mathbf{b})$$

$$\mathbf{a} \leftrightarrow \mathbf{b} \iff \langle \mathbf{a} \rangle = \langle \mathbf{b} \rangle, \quad (\mathbf{a} \text{ and } \mathbf{b} \text{ co-occur})$$

$$\mathbf{a} \rightarrow \mathbf{b} \iff [\langle \mathbf{a} \rangle \subset \langle \mathbf{b} \rangle \wedge \langle \mathbf{a} \rangle \neq \langle \mathbf{b} \rangle], \quad (\mathbf{a} \text{ implies } \mathbf{b})$$

$$\mathbf{a} \leftarrow \mathbf{b} \iff [\langle \mathbf{a} \rangle \supset \langle \mathbf{b} \rangle \wedge \langle \mathbf{a} \rangle \neq \langle \mathbf{b} \rangle], \quad (\mathbf{b} \text{ implies } \mathbf{a})$$

$$\mathbf{a} \perp \mathbf{b} \iff \langle \mathbf{a} \rangle \setminus \langle \mathbf{b} \rangle, \langle \mathbf{a} \rangle \cap \langle \mathbf{b} \rangle, \langle \mathbf{b} \rangle \setminus \langle \mathbf{a} \rangle \neq \emptyset.$$

(\mathbf{a} and \mathbf{b} are formally independent)

$$\mathbf{M}(\mathbf{v})_{\mathbf{ab}} := \mathbf{R} \iff \mathbf{a} \mathbf{R} \mathbf{b}$$

An example

$$F(\textit{przytapać}) = \left\{ \begin{array}{l} \{\textit{np(nom)}, \textit{np(acc)}\}, \\ \{\textit{np(nom)}, \textit{np(acc)}, \textit{na+np(loc)}\}, \\ \{\textit{np(nom)}, \textit{sie}, \textit{na+np(loc)}\} \end{array} \right\}$$

$M(\textit{przytapać})$	np(nom)	np(acc)	sie	na+np(loc)
np(nom)	↔	←	←	←
np(acc)	↑	↔	×	⊥
sie	↑	×	↔	⊥
na+np(loc)	↑	⊥	⊥	↔

A comparison of matrices (Bańko vs. Świdziński)

The numbers of triplets $(\mathbf{v}, \mathbf{a}, \mathbf{b})$ with the given values of $\mathbf{M}(\mathbf{v})_{\mathbf{ab}}$:

		Bań.					N/A
		×	←	→	↔	⊥	
Świ.	×	364	2	2	–	30	724
	←	4	253	1	2	18	176
	→	4	1	253	2	18	176
	↔	–	25	25	410	2	124
	⊥	16	6	6	–	28	38
	N/A	1242	230	230	167	102	

High agreement rate

The numbers of triples $(\mathbf{v}, \mathbf{a}, \mathbf{b})$ in the pairs of dictionaries:

	Σ	same $M(\mathbf{v})_{ab}$	different $M(\mathbf{v})_{ab}$	agreement rate
in Bań. & Pol.	1383	1187	196	86%
in Bań. & Świ.	1472	1308	164	89%
in Pol. & Świ.	1449	1283	166	89%

Valence dictionaries report quite different sets of arguments for a given verb. Nevertheless, combinations of the arguments that appear in several dictionaries are constrained similarly.

The most frequent values of matrix cells

	np(nom)	np(acc)	advp	np(dat)	np(inst)	w+np(loc)	do+np(gen)	na+np(acc)	z+np(gen)
np(acc)	↑:66%								
adv	↑:94%	↑:57%							
np(dat)	↑:91%	↑:50%	×:72%						
np(inst)	↑:98%	↑:57%	×:85%	×:64%					
w+np(loc)	↑:91%	↑:61%	×:92%	×:71%	×:85%				
do+np(gen)	↑:94%	↑:48%	×:92%	×:80%	×:89%	×:100%			
na+np(acc)	↑:96%	↑:64%	×:96%	×:85%	×:86%	×:90%	×:100%		
z+np(gen)	↑:100%	↑:65%	×:94%	×:91%	×:100%	×:100%	×:92%	×:100%	
ZE	↑:91%	×:76%	×:86%	⊥:64%	×:100%	×:100%	×:80%	×:71%	⊥:100%

$M(\mathbf{v})_{ab}$ for fixed arguments \mathbf{a} and \mathbf{b} depends weakly on verb \mathbf{v} .

Pruning of the proto-dictionary

- 1 Compute $\mathbf{L}(\mathbf{v})$ and $\mathbf{E}(\mathbf{v})$ for $\mathbf{F}(\mathbf{v})$ given by the proto-dict.
- 2 Correct $\mathbf{L}(\mathbf{v})$ and $\mathbf{E}(\mathbf{v})$. Then reconstruct

$$\mathbf{F}(\mathbf{v}) := \{(\mathbf{f} \cup \mathbf{E}(\mathbf{v})) \cap \mathbf{L}(\mathbf{v}) \mid \mathbf{f} \in \mathbf{F}(\mathbf{v})\}.$$

- 3 Compute $\mathbf{M}(\mathbf{v})$ for the current $\mathbf{F}(\mathbf{v})$.
- 4 Correct $\mathbf{M}(\mathbf{v})$. Then reconstruct

$$\mathbf{F}(\mathbf{v}) := \left\{ \mathbf{f} \in 2^{\mathbf{L}(\mathbf{v})} \mid \begin{array}{l} \forall \mathbf{a} \in \mathbf{E}(\mathbf{v}) \ \mathbf{a} \in \mathbf{f}, \\ \forall \mathbf{a}, \mathbf{b} \in \mathbf{L}(\mathbf{v}) \ \phi(\mathbf{f}, \mathbf{M}(\mathbf{v}), \mathbf{a}, \mathbf{b}) \end{array} \right\},$$

where

$$\phi(\mathbf{f}, \mu, \mathbf{a}, \mathbf{b}) := \begin{cases} \neg(\mathbf{a} \in \mathbf{f} \wedge \mathbf{b} \in \mathbf{f}), & \mu_{\mathbf{a}\mathbf{b}} = \times, \\ \mathbf{a} \in \mathbf{f} \iff \mathbf{b} \in \mathbf{f}, & \mu_{\mathbf{a}\mathbf{b}} = \leftrightarrow, \\ \mathbf{a} \in \mathbf{f} \implies \mathbf{b} \in \mathbf{f}, & \mu_{\mathbf{a}\mathbf{b}} = \rightarrow, \\ \mathbf{a} \in \mathbf{f} \longleftarrow \mathbf{b} \in \mathbf{f}, & \mu_{\mathbf{a}\mathbf{b}} = \leftarrow, \\ \text{true}, & \mu_{\mathbf{a}\mathbf{b}} = \perp. \end{cases}$$

Pruning of the argument sets

Argument **a** is recognized as **possible** for verb **v** if

$$c(\mathbf{v}, \mathbf{a}) \geq p_a c(\mathbf{v}) + 1,$$

and then **a** is recognized as **required** for **v** unless

$$c(\mathbf{v}) - c(\mathbf{v}, \mathbf{a}) \geq p_{\neg a} c(\mathbf{v}) + 1,$$

where

- $c(\mathbf{v}, \mathbf{a})$ — the count of parses that contain both **a** and **v**,
- $c(\mathbf{v})$ — the count of parses that contain **v**,
- p_a and $p_{\neg a}$ — parameters tuned to minimize the error rate on the training set.

Pruning of the co-occurrence matrices

- S — relation $\mathbf{M}(\mathbf{v})_{ab}$ in the raw matrix
- R — the most frequent relation between \mathbf{a} and \mathbf{b}
in the training set across different verbs

	agreement rate
$\mathbf{M}(\mathbf{v})_{ab} := S$	77%
$\mathbf{M}(\mathbf{v})_{ab} := R$	80%
$\mathbf{M}(\mathbf{v})_{ab} := T$	83%

- $T = \begin{cases} R, & \mathbf{C}(\mathbf{a} R \mathbf{b}) \geq p_{S \Rightarrow R} \mathbf{C}(\mathbf{a} \mathbf{b}) + t_{S \Rightarrow R}, \\ S, & \text{otherwise,} \end{cases}$
- $\mathbf{C}(\mathbf{a} \mathbf{b})$ — the number of verbs which select for \mathbf{a} and \mathbf{b}
- $\mathbf{C}(\mathbf{a} R \mathbf{b})$ — the number of verbs for which $\mathbf{a} R \mathbf{b}$
- $p_{S \Rightarrow R}$ and $t_{S \Rightarrow R}$ — optimized parameters

- 1 Introduction
- 2 Our method
- 3 Evaluation

A comparison with an earlier experiment

Fast and Przepiórkowski (2005):

- valence extracted from the IPI PAN Corpus (12 mln words),
- shallow parser,
- Brent's (1993) method (BMP),
- training and testing on Świdziński's dictionary,
- only NP and PP arguments.

	REC	PRE
Fast i Przepiórkowski (2005)	48%	49%
our results (projected onto NPs and PPs)		
— proto-dictionary	73%	19%
— after argument pruning	48%	64%
— after the co-occurrence matrix correction	43%	74%
— BMP reapplied	33%	85%

Some drawbacks of our method

- The distribution of false positives:

FP	all	argument climbing	test set errors
np(acc)	9	4	1
sie	4	0	4
np(dat)	11	3	6

- Our correction makes many cells of co-occurrence matrices independent of the verb.
- Exclusion **ZE × np(nom)** that holds under the absence of *sie* is atypical and impossible to describe:

$$\mathbf{F}(\text{dziwić}) = \left\{ \begin{array}{l} \{\text{np(nom), np(acc)}\}, \\ \{\text{ZE, np(acc)}\}, \\ \{\text{np(nom), sie}\}, \\ \{\text{np(nom), sie, np(dat)}\}, \\ \{\text{np(nom), sie, ZE}\} \end{array} \right\}$$

A comparison with three test dictionaries

The numbers of pairs (**v, f**):

The numbers of pairs (**v, a**):

a) after the correction of co-occurrence matrix:
